1. INTRODUCTION

Most international institutions responsible for publishing fisheries statistics (FAO, ICES, NAFO, etc.) require that data of the weight of landed catch be reported as the whole or live weight of the fish. To obtain this information directly is often impossible since fishermen eviscerate the fish either wholly or partially, immediately after capture to preserve them in good condition. With some types of vessels and with some species, further processing such as heading or filleting and freezing may also be carried out at sea. Hence, the quantity that is reported is often the weight of fish in any one of a number of different landed presentations. Clearly, before these can be presented for publication some factor or factors are needed to convert these landed weights into the required ones of whole weight. Equally clearly, such factors are different for each species and for each different form of landed presentation.

Landings statistics for England and Wales are processed and submitted to international organisations in this way using conversion factors that have been in use and remained unchanged for many years. The origins of these factors in many cases are uncertain, the data used to determine them having been either unrecorded, lost or destroyed. It is suspected, however, that for some species the factors that have been used were not based on observed data but were 'derived' from those used for other, similar species. Thus a single conversion factor has been in use for a number of roundfish species for many years and, similarly, a common single factor has been used for many of the flatfish.

With such uncertainties as to origin and accuracy, together with a present need for rapid accurate calculation of total weights for quota management implementation, it was thought appropriate to review the conversion factors for all the commercial species commonly landed in the UK. Consequently, during the past few years data have been collected whenever fresh whole fish have been available and suitable conditions for doing the work have prevailed. The results of this work are presented here.

2. METHODS

Consideration was given to those factors that could have significant influence on the relationship between whole and landed weights. The more important of these were thought to be:

- (i) seasonal variations in body condition particularly in large sexually mature fish;

- (ii) fish size;
- (iii) sex;
- (iv) stock or area of origin.

Whilst it was clear that the first three of these factors would probably have considerable bearing on results it was by no means obvious in the case of the last. Also, it was obvious that to extend the study to try to accommodate any possible stock differences would be to enlarge it to one of unmanageable size. Hence, it was decided that data for the same species would be combined, irrespective of area of origin. To accommodate the other considerations it was decided to:

- (i) obtain data for each quarter of the year separately, i.e. Jan-Mar, Apr-Jun, Jul-Sept, Oct-Dec;
- (ii) obtain data for the complete length range of each species, setting objectives of preferred minimum numbers for each 5 cm length group;
- (iii) obtain data for both sexes equally.

Because the numbers required were so large - 20 fish/length group/sex/quarter year were considered to be a practical minimum - it was found that in most cases sufficient fish could not easily be obtained in any one quarter of a single year. Hence, the results presented here are usually aggregated data obtained in a number of different years between 1978 and 1982.

It was an important requirement that fish for this study should be both fresh and whole. This sets constraints on sources for obtaining material. Ideally, measurements and weights should be taken as soon as possible after capture but to do so presented considerable difficulties. Accurate weighting - to the nearest gram - is rarely possible at sea because all balances are affected by ship's motion and perfectly still conditions seldom prevail. Hence, it was not possible to use freshly caught fish aboard normal fishing commercial vessels. Likewise, because of the long duration of most commercial voyages it was not possible to preserve whole fish in quantity from these catches for processing later ashore. The one exception to this was spurdogfish. These are often landed whole at a number of British fish markets from short duration (1-2 days) voyages. Thus, all the spurdogfish data were obtained from fish landed fresh this way at Lowestoft market.

Occasions were found when fishermen, carrying out very short (less than 12 hours) voyages, were prepared to bring back to port whole fish specially selected for the work. These were then measured and weighed ashore immediately after the ship returned. All of the data for sole,

pout whiting and thornback ray were obtained in this way; for lemon sole and pollack, approximately 90% of the data were obtained from this source.

For all of the remaining species, fish were obtained almost exclusively from research vessel catches. Two different methods were used to process these fish depending largely on the area of capture. When the ship was fishing grounds close to a sheltered anchorage, all of the fish required for this study that were caught during the day were retained whole on board in cool conditions. At the end of fishing operations each day the ship proceeded to anchorage where, in still conditions, measurements and weighings were made with the required accuracy. The maximum period that any fish was held between capture and weighing was 18 hours.

Where fish were taken on distant grounds, when conditions were unsuitable to make observations immediately, specimens were selected and quick frozen as soon as possible after capture. When this method was employed, each fish was measured and then kept separate in a plastic bag before freezing. At the end of each cruise the fish were returned to the laboratory and, after thawing, the appropriate weights were obtained. With this method the fish length, as measured at sea, was taken as the true length. A minor variation to this procedure, employed on some occasions, was to dissect specimens at sea immediately after capture in order to facilitate the weighing process ashore. When this practice was used, each separate component of the whole fish (i.e. head, body, viscera, stomach/intestine contents) was sealed in individual plastic bags within one large bag and then frozen.

The observations made for each individual fish were as follows:

- (a) species;
- (b) time of capture = year and quarter;
- (c) area of capture = ICES division;
- (d) total length, measured to the nearest centimetre below, i.e.
45 cm = 45.0 to 45.9 cm;
- (e) sex and maturity stage;
- (f) whole weight = as caught;
- (g) evacuated weight = as for whole fish but with the contents of stomach and intestine removed;
- (h) gutted weight = eviscerated according to the usual commercial practice, i.e. for roundfish total removal of the contents of the body cavity including gonads, for flatfish total removal of the same but excepting the gonads;

- (j) other weights = various other presentations involving further processing before landing and used in commercial practice for particular species, i.e:
- (i) various gadoids are occasionally landed gutted, (h) above, but with the head removed. Fish in this condition are referred to throughout as 'headless';
 - (ii) monkfish or anglers are usually landed gutted and with the head removed by severing the body as close as possible to the anterior end of the vertebral column. Fish in this condition are referred to throughout as 'monkfish tails';
 - (iii) spurdogfish are occasionally landed totally processed with heads, tails and dorsal fins removed and the body then skinned. Fish in this condition are referred to throughout as 'spurdogfish tails';
 - (iv) skates and rays are often landed with the central body section and the tail completely removed. Fish in this condition are referred to throughout as 'wings'.

All weights were made to the nearest gram. In preparing fish for weighing, in all the presentations outlined above under (j), the customary commercial practices of cutting the fish have been followed as closely as possible.

3. DATA PROCESSING

Data were analysed using the Ministry's ICL 2966 computer. The analysis was broken down into three sections:

- A data validation;
- B updating of individual species data files;
- C calculation of simple statistics for lengths, weights, conversion factors, condition factors, and the determination of weight-length relationships;

Validation covered the sample descriptive information, e.g. species identification code, sampling area, time of capture, as well as individual fish data. The latter had the following checks made on them:

- (a) lengths to lie in the range 15-150 cm;
- (b) weights to be in the order whole > evacuated > gutted > 'other';
- (c) condition factors ($\text{weight} \times 100 / (\text{length})^3$) to lie within $\pm 50\%$ of given condition factor values for the respective presentation, while checks were also made on maturity stage (1-8) and sex code (M/F/U - male, female and unsexed respectively) values.

Within each sample data were sorted into female, male or unsexed categories and then arranged in length order, before being written to the species data file where they were held by year, period and area of capture.

The following statistics were derived for each 5 cm group within the length distribution:

- (i) Mean length. As the fish lengths were recorded to the nearest centimetre below total length, 0.5 was added to convert the raw length values to measurements to the nearest centimetre (the assumption being that within each centimetre interval values are evenly spaced and will take, on average, the mid-interval value). In all subsequent calculations involving length, the adjusted and not the raw length values were used.
- (ii) Mean weight and standard deviations.
- (iii) Mean conversion and condition factors with their standard deviations and coefficients of variation ($\frac{\text{standard deviation}}{\text{mean}} \times 100\%$). Up to six conversion factors (dependent on the number of presentations for a species) were estimated, namely
whole/evacuated evacuated/gutted gutted/other
whole/gutted evacuated/other
whole/other
while condition factors were derived for all weight types.

The above statistics were derived by quarter for sexed and unsexed categories. These estimates were based on individual fish observations, such that the average factor for a length group was the arithmetic mean of all the individual fish factor estimates within the group. Corresponding annual estimates were determined as follows:

$$\bar{x}_{i.} = \frac{\sum_{j=1}^4 \bar{x}_{ij}}{m} \quad (1)$$

$$SD_{i.} = \sqrt{\frac{\sum_{j=1}^4 \sigma_{ij}^2}{m} + \frac{\sum_{j=1}^4 (\bar{x}_{ij} - \bar{x}_{i.})^2}{m}} \quad (2)$$

where $\bar{x}_{i.}$ = length group i annual mean

\bar{x}_{ij} = " " " " standard deviation

\bar{x}_{ij} = " " " " quarter j mean

σ_{ij}^2 = " " " " variance

m = number of quarters sampled.

(note if quarter j is not sampled then $\bar{x}_{ij} = 0 = \sigma_{ij}^2$ in equations (1) and (2)).

In addition to individual 5 centimetre grouping values, estimates of means, standard deviations and coefficients of variation were also determined on a total sample basis for the conversion and condition factors.

$$\text{i.e. } \bar{X}_{\cdot j} = \frac{\sum_{i=1}^L n_{ij} \bar{x}_{ij}}{N} \quad (3)$$

$$SD_{\cdot j} = \sqrt{\frac{\sum_{i=1}^L ((n_{ij}-1)\sigma_{ij}^2 + n_{ij} \bar{x}_{ij}^2) - N\bar{X}_{\cdot j}^2}{N-1}} \quad (4)$$

where $\bar{X}_{\cdot j}$ = quarter j sample mean

$SD_{\cdot j}$ = " " " variance

n_{ij} = " " length group i sample size

N = total sample size = $\sum_{i=1}^L n_{ij}$

L = number of 5 cm groupings in quarter j length distribution while corresponding values were also derived on an annual basis as before.

Finally quarterly and annual weight-length relationships

$$W = aL^b \quad (5)$$

where W = whole weight (g)

L = (measured) length + 0.5 (cm)

were determined by sex and for sexes combined. The calculation of an estimate of the standard error of b enables the departure of b from the assumed cubic value to be examined via the t-test. Furthermore, these values also readily lend themselves to be used in a comparison of quarterly weight-length relationships to illustrate any sex/seasonal difference. In general, variations in b values were seasonal (values increasing in magnitude in the quarterly sequence 3, 2, 1, 4) with limited sex variation.

The computer analysis permits the processing of species data to be carried out either on a selected areas or all areas combined basis.

4. RESULTS

Because of the variability in availability of different species, comprehensive data sets have been obtained for the more common species such as cod, haddock, spurdogfish and plaice, while for some species, data are scant, representing only a few fish. A list of the 27 species included in the present study, together with the total number of specimens examined is

given in Table 1. Despite the paucity of data in some cases it is considered appropriate to publish all the results now with the proviso that more data will be obtained whenever possible for the poorly represented species and that further updating may be made from time to time.

From these data the relationship between whole weight and the weight of various landed presentations, appropriate to each species, have been determined. These results are summarised in Table 2 which shows conversion factors for each species relating each presentation to whole weight. For each species a single factor is given for each relationship, these being derived by combining data for fish of all sizes, for both sexes, for all periods of the year and from all areas. In all cases the values are given to two decimal places and are considered to be appropriate factors for regular use in the conversion of landings statistics for publication.

The data have also been used to determine condition factors for each species, based upon whole weight and following the equation

$$W = aL^b$$

A summary of these results is given in Table 3 which shows values for the coefficient 'a' when $b = 3$ (the cubic relation) and for both 'a' and 'b' as derived from the fitted regression of whole weight on length. These values have also been obtained by combining data for fish of all sizes, of both sexes, for all periods of the year and from all areas.

Also determined and presented here are detailed results showing the effect of fish size on various relationships. These appear in Tables 4-30 where, for each 5 cm length group covering the length range of each species, three tables have been prepared for each showing:

- (a) the number of fish sampled, mean length, and mean weight for each form of presentation;
- (b) factors for conversion from one form of presentation to another, together with overall (all length groups combined) average factors;
- (c) condition factors for each form of presentation using the relationship $W = aL^b$ together with overall average condition factors.

In all of these tables data for both sexes, for all periods of the year, and from all areas are combined to determine the values given.

Finally separate tables have been prepared to the same format as in a, b, and c, above but in greater detail, giving values for each sex separately and for each quarter of the year (i.e. 8 tables). For reasons of space and their limited application these tables are not included here but are available on request if required for particular precise application.

Table 1 Species included in the study

English name	Scientific name	Number of specimens
1. Cod	<u>Gadus morhua</u>	1 033
2. Haddock	<u>Melanogrammus aeglefinus</u>	793
3. Whiting	<u>Merlangius merlangus</u>	393

LENGTH - WEIGHT CONSTANTS (W=AL**B)

B = 3.542 A = .00216 CORR. COEFF. = .987
 STD ERROR (B) = .0011
 T TEST FOR SIGNIFICANCE OF DIFFERENCE OF B FROM 3 = 6.68
 DEGREES OF FREEDOM = 52

Previous issues in the Data Report series:

1. NEADS 6 first deployment, October 77-June 78 (1983).
2. Current meter observations from the Charlie-Gibbs Fracture Zone (1984).
3. Current meter observations from the Porcupine Abyssal Plain, June 1979-June 1980 (1985).
4. Current meter observations near the Sellafield pipeline, May 1981-December 1983 (1985).
5. Salmon and migratory trout fisheries statistics for England and Wales, 1983 (1985).
6. Marine environment data inventory for the Bay of Biscay, Celtic Sea and West of Ireland, March-July 1977 (1985).
7. Salmon and migratory trout fisheries statistics for England and Wales, 1984 (1985).
8. Current meter observations near the Porcupine Bank, 1981-1983 (1986).
9. Salmon and migratory trout fisheries statistics for England and Wales, 1985 (1986).
